

UK Energy Consumption - Strong Task 1

Sample Submission for IELTS Writing Evaluation

The bar chart illustrates the changes in energy consumption from five different sources in the United Kingdom between 1970 and 2000. Overall, it is evident that coal experienced the most dramatic decline over the period, while natural gas emerged as the dominant energy source by 2000. In 1970, coal accounted for the largest share of energy consumption at approximately 40%, however this figure fell sharply to around 18% by the end of the period. Conversely, the consumption of natural gas rose considerably from roughly 15% in 1970 to become the leading source at nearly 38% in 2000. Oil remained relatively stable throughout, fluctuating between 30% and 35%, whereas nuclear energy, despite showing modest growth, continued to represent the smallest proportion at approximately 8% by 2000.
